

**T20/DP178 AND T21/DP107 ARE ACTIVATORS OF HUMAN PHAGOCYTE
FORMYL PEPTIDE RECEPTORS**

5

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of international application number PCT/US00/12371, and claims the benefit of priority of international application number PCT/US00/12371 having international filing date of May 5, 2000, designating the United States of America and published in English, which claims the benefit of priority of U.S. provisional patent application no. 60/132,686, filed May 5, 1999; both of which are hereby expressly incorporated by reference in their entireties.

10

FIELD OF THE INVENTION

15

The present invention relates to the discovery that T20/DP178, T21/DP107, and fragments thereof interact with members of the formyl peptide receptor family and thereby modulate cell migration and activation. Novel biological tools, prophylactics, therapeutics and methods of use of the foregoing for modulating an inflammatory response are disclosed.

20

BACKGROUND OF THE INVENTION

25

30

The envelope proteins of human immunodeficiency virus type 1 (HIV-1) are synthesized in the form of a precursor, gp160, which is subsequently cleaved by proteinases to yield mature proteins gp120 and gp41. (Kowalski et al., *Science* 237: 1351 (1987)). Gp120 is noncovalently bound to the extracellular domain of gp41 and mediates viral binding to host cells through high affinity interaction with CD4 receptors, followed by interaction with chemokine receptors which have recently been identified as HIV-1 fusion co-factors. (Dimitrov and Broder, *HIV and Membrane Receptors, HIV and membrane fusion*. Medical Intelligence Unit, Landes Bioscience, Austin, TX (1997); and Berger, *AIDS* 11, Suppl A: S3 (1997)). The viral envelope gp41 plays a critical role in fusion of HIV-1 and host cell membranes. (Dimitrov and Broder, *HIV and Membrane Receptors, HIV and membrane fusion*. Medical

Intelligence Unit, Landes Bioscience, Austin, TX (1997); and Berger, *AIDS* 11, Suppl A: S3 (1997)).

Structural analysis predicts the gp41 ectodomain to contain two segments as extended helices. (Chan et al., *Cell* 89: 263 (1997)). One segment, termed T21/DP107 in the NH₂-terminus has a leucine zipper like motif, whereas another segment T20/DP178 is located in the carboxyl terminus of the gp41 ectodomain. In the absence of gp120 and the N-terminal fusion domain, the ectodomain of gp41 forms a soluble α -helical rodlike oligomer. (Chan et al., *Cell* 89: 263 (1997) and Lawless et al., *Biochemistry* 35: 13697 (1996)). The peptide segment T20/DP178, located in the C-terminus of the ectodomain of gp41, interacts with the N-terminal leucine zipper-like domain on gp41 to establish the fusogenic conformation of the virus. Synthetic analogues of both T21/DP107 and T20/DP178 have been shown to inhibit virus-mediated cell-cell fusion and to reduce the infectious titer of cell-free virus. (Lawless et al., *Biochemistry* 35: 13697 (1996); Lawless et al., *Biochemistry* 35: 13697 (1996); Kazmierski et al., *J. Med. Chem.* 39: 2681 (1996); Chen et al., *J. Virol.* 69: 3771 (1995); Sabatier et al., *Virology* 223: 406 (1996); Kliger et al., *J. Biol. Chem.* 272: 13496 (1997); and Munoz-Barroso et al., *J. Cell. Biol.* 140: 315 (1998)). Although T21/DP107 and T20/DP178 peptides have been shown to inhibit HIV-1- fusion, other biological and biochemical interactions involving these peptides or fragments thereof have not been identified.

BRIEF SUMMARY OF THE INVENTION

Patients suffering with AIDS have monocytes which exhibit a reduced migratory response when stimulated with a variety of chemoattractants *in vitro*. (Smith et al., *J. Clin. Invest.* 74: 2121 (1984)). Exposure of human monocytes to either HIV-1 envelope proteins gp120 or gp41, inhibits their chemotactic responses to a wide variety of chemoattractants including the bacterial chemotactic peptide *N*-formyl-methionyl-leucyl-phenylalanine (fMLP) and a number of recently defined chemokines through a mechanism resembling heterologous "desensitization". (Wang et al., *J. Immunol.* 161: 4309 (1998); and Ueda et al., *J. Clin. Invest.* 102: 804 (1998)). In order to further define the structural basis for the capacity of HIV-1 envelope proteins to "desensitize"

host cells, we have evaluated the effects of selected peptide segments of gp41 on human immune cells.

In the disclosure that follows, we report our discovery that T20/DP178 and T21/DP107 interact with members of the formyl peptide receptor family (collectively referred to as "FPR class" or "FPR members") and thereby up-regulate an inflammatory response. The FPR class includes members such as the *N*-formyl peptide receptor (FPR) and the *N*-formyl peptide receptor-like 1 (FPRL1) molecules and more family members may be identified in the future, for example, by comparing regions of homology which are readily identified in the sequence of FPR and FPRL1. By interacting with an FPR member, T20/DP178 and T21/DP107 act as both potent chemoattractants and activators of human peripheral blood phagocytes (monocytes and neutrophils) but not T lymphocytes. Our discovery that T20/DP178 and T21/DP107 induce cell migration and calcium mobilization in cells by interacting with an FPR member is based on several experiments using cells transfected to express these proteins. In the experiments and discussion presented below, we demonstrate that the T20/DP178- and T21/DP107-induced activation of phagocytes is pertussis toxin sensitive and that fMLP does not induce significant chemotaxis of FPRL1 expressing cells at concentrations as high as 50 μ M. Further, we show that a lipid metabolite, lipoxin A4 (a high affinity ligand for FPRL1), is not able to induce Ca^{++} mobilization or chemotaxis in FPRL1 expressing cells.

Additionally, we have discovered that synthetic T20/DP178 analogs which lack N-terminal amino acids interact with an FPR member and thereby down-regulate an inflammatory response. Accordingly, T20/DP178 truncated variants are antagonists for FPR member-mediated chemoattraction and activation. Novel biological tools, prophylactics, and therapeutics comprising T20/DP178, T21/DP107 and fragments thereof, as well as, methods of use of the foregoing for modulating an inflammatory response are disclosed.

BRIEF DESCRIPTION OF THE DRAWINGS

FIGURE 1A shows the fold increase of leukocyte migration in response to T20/DP178 over control medium (the CI or chemotaxis index).

FIGURE 1B shows that the induction of monocyte migration mediated by T20/DP178 is inhibited by pretreatment of cells with pertussis toxin ("PT") at 100 ng/ml for 30 min at 37 °C but not cholera toxin ("CT").

- 5 FIGURE 2A shows the induction of calcium (Ca^{++}) mobilization in human monocytes loaded with Fura-2 and stimulated with different concentrations of T20/DP178; the ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.
- 10 FIGURE 2B shows the induction of calcium (Ca^{++}) mobilization in neutrophils loaded with Fura-2 and stimulated with different concentrations of T20/DP178; the ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.
- 15 FIGURE 2C1 shows that fMLP (100 nM) desensitizes calcium (Ca^{++}) mobilization in human monocytes loaded with Fura-2 and stimulated with T20/DP178 (100 nM); the ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.
- 20 FIGURE 2C2 shows that T20/DP178 (100 nM) desensitizes calcium (Ca^{++}) mobilization in human monocytes loaded with Fura-2 and stimulated with fMLP (100 nM); the ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.
- 25 FIGURE 2C3 shows that T20/DP178 (100 nM) desensitizes calcium (Ca^{++}) mobilization in neutrophils loaded with Fura-2 and stimulated with fMLP (100 nM); the ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.
- 30 FIGURE 2C4 shows that fMLP (100 nM) desensitizes calcium (Ca^{++}) mobilization in neutrophils loaded with Fura-2 and stimulated with T20/DP178 (100 nM); the ratio of

fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.

FIGURE 3A shows that different concentrations of T20/DP178 can induce Ca^{++} mobilization in a rat basophil cell line (ETFR) that was transfected to express FPR.

FIGURE 3B1 shows that fMLP (100 nM) desensitizes Ca^{++} mobilization in ETFR cells transfected to express FPR and stimulated with T20/DP178 (1 μM).

FIGURE 3B2 shows that T20/DP178 (1 μM) desensitizes Ca^{++} mobilization in ETFR cells transfected to express FPR and stimulated with fMLP (100 nM).

FIGURE 3C shows that T20/DP178 did not induce Ca^{++} mobilization in mock-transfected parental cells.

FIGURE 3D shows the induction of migration of ETFR cells that were transfected to express FPR by T20/DP178 and fMLP over a range of concentrations (the CI or chemotaxis index).

FIGURE 3E shows the induction of migration of mock-transfected ETFR cell by T20/DP178 and fMLP over a range of concentrations (the CI or chemotaxis index).

DETAILED DESCRIPTION OF THE INVENTION

In the disclosure below, we teach that several ligands interact with FPR members including, but not limited to, T20/DP178, T21/DP107, and fragments thereof. We have discovered that a novel complex comprising T20/DP178, T21/DP107, or a fragment thereof joined to an FPR member up-regulates or down-regulates an inflammatory response, as marked by chemoattraction and cell activation. We contemplate that the sequence of T20/DP178, T21/DP107, and fragments thereof, as well as, protein models of T20/DP178, T21/DP107, and fragments thereof can be used to identify many more ligands which interact with an FPR member and thereby induce a desired inflammatory response. Thus, many more novel FPR member-ligand complexes can be identified. Several embodiments of the present invention, therefore, include T20/DP178, T21/DP107, and fragments thereof in biotechnological tools for use in discovering a new class of anti-inflammatory agents or agents which modulate an inflammatory response. Other embodiments include therapeutic and prophylactic agents which comprise T20/DP178, T21/DP107, and fragments thereof for use in the treatment and/or prevention of conditions associated with either an impotent inflammatory response or a potent inflammatory response.

The *N*-formyl peptide receptor (FPR) and its variant FPR-like 1 (FPRL1), are members of a family of receptors referred to as "FPR class" or "FPR members". The

FPR class are G-protein-coupled receptors which have seven transmembrane domains. FPR members are typically found on human phagocytic cells but they have also been identified on hepatocytes, and cytokine stimulated epithelial cells. Many other cell types may have FPR members. FPR members interact with chemotactic *N*-formyl peptides. (Prossnitz and Ye, *Pharmacol. Ther.* 74: 73 (1997); Murphy, *The N-formyl peptide chemotactic receptors*, Chemoattractant ligands and their receptors. CRC Press, Boca Raton, p. 269 (1996)). FPR and FPRL1 are expressed by monocytes and neutrophils and are clustered on human chromosome 19q13. (Bao et al., *Genomics* 13: 437 (1992); and Durstin et al., *Biochem. Biophys. Res. Commun.* 201: 174 (1994), herein both references are expressly incorporated by reference). FPRL1 was identified and molecularly cloned from human phagocytic cells by low stringency hybridization of the cDNA library with the FPR sequence and was initially defined as an orphan receptor. (Gao and M. Murphy, *J. Biol. Chem.* 268: 25395 (1993); Murphy et al., *J. Biol. Chem.* 267: 7637 (1992); Ye et al., *Biochem. Biophys. Res. Commun.* 184: 582 (1992) and Nomura et al., *Int. Immunol.* 5: 1239 (1993), herein all references are expressly incorporated by reference). The cloning of the same receptor termed FPRH2 from a genomic library was also described. (Bao et al., *Genomics* 13: 437 (1992), herein expressly incorporated by reference). FPRL1 possesses 69% identity at the amino acid level to FPR. (Prossnitz and Ye, *Pharmacol. Ther.* 74: 73 (1997); and Murphy, *The N-formyl peptide chemotactic receptors*, Chemoattractant ligands and their receptors. CRC Press, Boca Raton, p. 269 (1996), herein both references are expressly incorporated by reference). Many more FPR members may be present and can be rapidly identified by using the cloning methods detailed in the references cited above and the functional assays described herein.

In the following, we disclose our discovery that T20/DP178 is a chemoattractant and activator of monocytes and neutrophils.

T20/DP178 is a chemoattractant and activator of monocytes and neutrophils

The synthetic T20/DP178 exhibited potent inhibition on fusion of both T lymphocyte tropic and monocyte tropic HIV-1, as reported previously. (Lawless et al., *Biochemistry* 35: 13697 (1996)). Its analog T716, T719, T712 showed significant but progressively reduced anti-HIV-1 activity, whereas T914 was ineffective on HIV-1

We next examined whether the T20/DP178-induced monocyte and neutrophil migration was due to activation of specific receptors. The migration of monocytes and neutrophils in response to T20/DP178 was completely inhibited by pretreatment of the cells with pertussis toxin, but not cholera toxin or herbimycin A (FIGURE 1B), demonstrating that a G-protein of the G_i type coupled receptor was involved. (Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy, *Annu. Rev. Immuno.* 12: 593 (1994); Oppenheim et al., *Annu. Rev. Immunol.* 9: 617 (1991); and Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996)).

The finding above was also supported by the induction of a dose-dependent, and pertussis toxin sensitive, calcium (Ca^{++}) mobilization in monocytes and neutrophils by T20/DP178. (FIGURES 2A-2B). Human monocytes or neutrophils were loaded with

Fura-2 and then were stimulated with T20/DP178. The ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program.

The capacity of T20/DP178 to desensitize cell response to subsequent stimulation with other chemoattractants was then tested to determine whether this peptide shared G-protein-coupled receptor(s) with other chemoattractants (FIGURES 2C1-2C4). T20/DP178 did not cross-desensitize the Ca^{++} flux induced by a number of chemokines including IL-8, MCP-1 (monocyte chemotactic protein-1), RANTES, MCP-3 (monocyte chemotactic protein-3), or MIP-1 α (macrophage inflammatory protein-1 α), thus, T20/DP178 does not share a receptor with any of these chemokines.

On the other hand, the bacterial chemotactic peptide fMLP had a marked desensitizing effect on T20/DP178-induced Ca^{++} mobilization in both monocytes (FIGURES 2C1 and 2C2) and neutrophils. (FIGURES 2C3 and 2C4). The desensitization of Ca^{++} flux between fMLP and T20/DP178 was unidirectional when both agonists were used at same concentration (100 nM), since T20/DP178 had negligible effect on subsequent fMLP stimulation. These results unequivocally demonstrate that T20/DP178 interacts with an FPR member and thereby mediates cell migration and cell activation. In the following, we discuss our discovery that T20/DP178 is a functional ligand for FPR members on phagocytic cells.

T20/DP178 is a functional ligand for FPR members on phagocytic cells

In order to verify whether T20/DP178 binds to one of the fMLP receptors, we tested the effect of T20/DP178 on a rat basophil leukemia cell line transfected with a cDNA encoding an epitope-tagged FPR, the first of the cloned seven transmembrane, G-protein-coupled receptors for fMLP. (Ali et al., *J. Biol. Chem.* 268: 24247 (1993); Ali et al., *J. Biol. Chem.* 271: 3200 (1996); Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy and McDermott, *J. Biol. Chem.* 266: 12560 (1991); and Oppenheim et al., *Ann. Rev. Immunol.* 9:617 (1991). T20/DP178 induced a dose-dependent Ca^{++} mobilization in ETFR cells transfected to express FPR with maximal stimulation at 1 μM concentration. (FIGURE 3A). Sequential stimulation of the FPR expressing ETFR cells with fMLP and T20/DP178 or vice versa resulted in bi-directional desensitization, with fMLP being more efficacious, since a higher dose of T20/DP178 was required to completely abolish the cell response to fMLP. (FIGURES 3B1 and 3B2). Neither

peptide stimulated Ca^{++} flux in parental cells or mock-transfected cells proving that the response was indeed mediated by FPR in the transfected ETFR cells and that this receptor played a major role in the unidirectional desensitization between fMLP and T20/DP178 in phagocytes. (FIGURE 3C).

5 Chemotaxis assays were then used as another sensitive biological parameter to assess the function of the FPR in FPR expressing ETFR cells, as in our previous studies with chemokine receptors. (Gong et al., *J. Biol. Chem.* 273: 4289 (1998); Gong et al., *J. Biol. Chem.* 272: 11682 (1997); and Ben-Baruch et al., *J. Biol. Chem.* 270: 22123 (1995)). ETFR cells were induced by fMLP to migrate across polycarbonate filters
10 coated with extracellular matrix protein, collagen type I, with an EC_{50} of about 500 pM, while T20/DP178 induced a more pronounced migration of the ETFR cells, although with lower potency (EC_{50} 5 nM) than fMLP. (FIGURE 3D). In contrast, T20/DP178 or fMLP did not induce migration of mock-transfected cells. (FIGURE 3E).

In order to confirm that T20/DP178 is acting at FPR, we used ligand binding
15 competition experiments with ^3H -labeled fMLP. T20/DP178 effectively competed with ^3H -fMLP for binding to FPR expressing ETFR cells, although with a less potency compared with unlabeled fMLP. (FIGURE 3F). The IC_{50} for T20/DP178 was about 5 nM and the IC_{50} for fMLP was about 1 nM, in agreement with the chemotactic and Ca^{++} mobilizing activity of both agonists for the FPR expressing ETFR cells.

20 Evidence that T20/DP178 is an FPR agonist was also provided by the detection of a rapid phosphorylation of FPR following stimulation of FPR expressing ETFR cells with T20/DP178. Phosphorylation of FPR was measured by incubating [^{32}P]-orthophosphate labeled ETFR cells with medium alone or T20/DP178 at 37°C for 15 min and an equivalent amount of cell lysate for each treatment was immunoprecipitated
25 with an anti-epitope (anti-HA) antibody. Immunoprecipitates were separated on a gel and a 65 kDa phosphorylated protein species was detected. This protein was identical to the phospho-protein detected in immunoprecipitates of fMLP treated cells.

It was also determined that T20/DP178 induced a time- and dose-dependent activation of mitogen activated protein kinase (MAPK) in human monocytes, a
30 signaling event that can be initiated by fMLP. (Krump et al., *J Biol Chem* 272:937 (1997); and Torres and Ye, *J Biol Chem* 271:13244 (1996)). MAPK activation was examined in human monocytes by treating the cells with different concentrations of

T20/DP178 at various time intervals followed by immunoprecipitation of cell lysates with an anti-p38 MAPK antibody. The immunoprecipitates were then separated on a gel and immunoblotted with a mouse anti-phosphotyrosine antibody. The immunoblot revealed that T20/DP178 induced phosphorylation of MAPK. These results clearly established that T20/DP178 was interacting with an FPR member and that this interaction induced Ca^{++} mobilization, signal transduction, and chemotaxis. In the disclosure below, we provide evidence that fragments of T20/DP178 are antagonists of FPR members.

Analogs of T20/DP178 are antagonists of FPR members

A number of FPR agonistic peptides have been reported. (Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy and McDermott, *J. Biol. Chem.* 266: 12560 (1991); Murphy, *Annu. Rev. Immuno.* 12: 593 (1994); Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996); and Gao et al., *J. Exp. Med.* 180: 2191 (1994)). However, T20/DP178 derived from HIV-1 gp41 does not bear any substantial sequence identity with the reported FPR agonistic peptides including the absence of an N-formyl group. By way of explanation only and not to limit any aspect of our present invention, we believe that it is the conformation of T20/DP178, rather than the primary sequence, that determines its activity. Thus, in several embodiments, we contemplate using FPR models and methods of rational drug design, preferably using "fuzzy functional forms" (FFF) -- a three-dimensional descriptor of the active site of a protein, to identify many more ligands which interact with FPR members. (See the discussion below and Fetrow et al., *J. Mol. Biol.* 282:703-711 (1998) and Fetrow and Skolnick, *J. Mol. Biol.* 281: 949-968 (1998), herein incorporated by reference).

In addition to T20/DP178, we tested 4 synthetic T20/DP178 analogs that lack 3 (T716), 5 (T719), 7 (T712), and 12 (T914) amino acids respectively at the N-terminus of T20/DP178. (FIGURES 4A1-A7 and 4B1-B6). Accordingly, monocytes or FPR-expressing ETFR cells were loaded with Fura-2 and then were sequentially stimulated with T20/DP178 analogs D719 or D712 (50 μM) and fMLP (100 nM) or T20/DP178 (100 nM). The chemokine MCP-1 (100 nM) was used as a control to indicate the specificity of D719 or D712. All the analogs failed to induce significant Ca^{++}

mobilization in monocytes or the FPR-expressing ETFR cells. Instead, they abolished Ca^{++} mobilization in response to subsequent T20/DP178 or fMLP stimulation in both types of phagocytic leukocytes and FPR-expressing ETFR cells but they did not affect monocyte response to chemokines such as MCP-1.

5 The synthetic T20/DP178 truncated analogs also specifically inhibited ^3H -fMLP binding and significantly attenuated migration of FPR-expressing ETFR cells that were induced by T20/DP178 and fMLP. (FIGURES 5A and 5B). In the binding study, different concentrations of DP719 or DP712 were added to aliquots of human monocytes containing a constant concentration of ^3H -fMLP. After incubation at 37°C 10 for 20 min, the cells were harvested and measured for β -emission. Unlabeled fMLP at $1\mu\text{M}$ was used as a positive control. The cell migration analysis was conducted by placing T20/DP178 ($1\mu\text{M}$) or fMLP (100 nM) in the lower wells of a chemotaxis chamber and FPR expressing ETFR cells at $1 \times 10^6/\text{ml}$ in the upper wells of the chamber in the presence or absence of $50\mu\text{M}$ DP917 or DP912. After incubation, the 15 cells that migrated across the filters were counted. The chemotactic index (CI), which determines the fold increase of migration over the medium (control) was calculated. $*P < 0.01$ (Student's t test) compared with the migration of cells incubated with medium alone. The migration experiments revealed that DP917 or DP912 did not affect the cell migration in response to medium alone nor did DP917 or DP912 induce ETFR cell 20 migration. These results provided evidence that deletion of 3-12 amino acids from the N-terminus of T20/DP178 produced FPR antagonists. In the following section, we describe our finding that the peptide T21/DP107 is a chemoattractant and activator of monocytes and neutrophils.

25 *T21/DP107 is a chemoattractant and activator of monocytes and neutrophils*

Initially, we tested whether synthetic T21/DP107 could induce human leukocyte migration, a crucial step for cell homing and accumulation at sites of inflammation or injury. Different concentrations of T21/DP107 ($1\mu\text{M}$ for microscopy experiments) were placed in the lower wells of a chemotaxis chamber and a cell suspension was 30 placed in the upper wells. fMLP (100nM) was used as a control. The upper and lower wells were separated by polycarbonate filters. After incubation, the cells that migrated across the filters were stained and counted. Microscopy of stained cells revealed that

both human peripheral blood monocytes and neutrophils migrated in response to 1 μ M T21/DP107. The chemotaxis analysis also revealed that monocytes and neutrophils migrate in a dose-dependent manner in response to a varying concentrations of T21/DP107. The fold increase of leukocyte migration in response to T21/DP107 over control medium (the CI index) was calculated and is shown in FIGURE 6A. The chemotactic activity of T21/DP107 was significant at nM concentrations for both monocytes and neutrophils and the cell response remained high with only slight reduction when T21/DP107 was used at 10⁻⁵ - 10⁻⁴ M. In contrast, human CD3+ T lymphocytes showed a marginally significant migration (CI = 2) in response to high concentrations (5 X 10⁻⁶ M and higher), proving that the effect of T21/DP107 was mainly on phagocytic cells. The analysis showed that monocytes migrated when higher concentrations of T21/DP107 were present in the lower wells of the chemotaxis chamber (TABLE 1).

TABLE 1

Checkerboard analysis of monocyte migration in response to T21/DP107^a

T21 in lower wells (M)	Number of migrated cells in 1HPF (mean \pm SE)			
	T21 in upper wells (M)			
	Medium	10 ⁻⁸	10 ⁻⁷	10 ⁻⁶
Medium	20 \pm 1	11 \pm 2	7 \pm 1	9 \pm 2
10 ⁻⁸	40 \pm 4 ^b	28 \pm 3	7 \pm 2	10 \pm 3
10 ⁻⁷	64 \pm 3 ^b	43 \pm 2 ^b	25 \pm 4	26 \pm 3
10 ⁻⁶	132 \pm 6 ^b	110 \pm 3 ^b	89 \pm 6 ^b	57 \pm 4 ^b

^a Different concentrations of T21/DP107 were placed in the upper and/or lower wells of the chemotaxis chamber, monocytes at 2 x 10⁶/ml were placed in the upper wells. The upper and lower wells were separated by a polycarbonate filter. After incubation, the non-migrating cells were removed and the filter was fixed, stained and the cells migrated across the filter were counted in three high powered fields (HPF, 400 x). The results are expressed as the mean value (\pm SE) of the cells 1 HPF. Similar results were obtained in two separate experiments.

^b P < 0.01 compared with migration in the presence of medium alone in both upper and lower wells as determined by Student's test.

Enhanced cell migration was not observed when higher concentrations of T21/DP107 were present in the upper wells. With equal concentrations of T21/DP107 in both upper and lower wells, a slightly increased monocyte migration was observed. These results prove that the cell migration induced by T21/DP107 resulted from a chemotactic effect, albeit chemokinesis contributed slightly.

FIGURE 6B further shows that monocyte migration in response to T21/DP107 can be inhibited by pretreatment of the cells with pertussis toxin ("PT") at 100 ng/ml for 30 min at 37 °C. That is, the migration of monocytes and neutrophils in response to T21/DP107 was completely inhibited by pretreatment of the cells with pertussis toxin, but not by cholera toxin or herbimycin A, proving that a G-protein of the Gi type coupled receptor was involved. (Prossnitz and Ye, *Pharmacol. Ther.* 74: 73 (1997); Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996); Murphy and McDermott, *J. Biol. Chem.* 266: 12560 (1991); Murphy, *Annu. Rev. Immunol.* 12: 593 (1994); Oppenheim et al., *Annu. Rev. Immunol.* 9: 617 (1991); and Gao et al., *J. Exp. Med.* 180: 2191 (1994)).

The finding above was further supported by the potent induction of a dose-dependent, and pertussis toxin sensitive, calcium (Ca^{++}) mobilization in monocytes and neutrophils by T21/DP107. The Ca^{++} mobilizing activity of T21/DP107 was significant at nM concentrations indicating that this synthetic peptide is a potent activator of human phagocytic cells. The possibility that byproduct(s) formed during peptide synthesis/purification might account for the activity of T21/DP107 was proven unlikely, since a fusion peptide (aa 517-532 of gp41) synthesized during the same period as T21/DP107 did not possess any chemotactic or Ca^{++} mobilizing activity in phagocytes. In the following section, we discuss our discovery that T21/DP107 is a functional ligand for FPR members on phagocytic cells.

T21/DP107 is a functional ligand for FPR members on phagocytic cells

In order to characterize the molecular nature of the receptor(s) on phagocytic cells which interact with T21/DP107, a series of cross-desensitization experiments were

performed using a variety of chemoattractants. (FIGURES 7A, 7B1, 7B2, 7C, 8D1, and 8D2). Accordingly, human monocytes or neutrophils were loaded with Fura-2 and then were stimulated with various concentrations of T21/DP107. The ratio of fluorescence at 340 nm and 380 nm wave length was recorded and calculated using the FLWinLab program. The desensitization of T21/DP107 (1 μ M) induced Ca^{2+} flux by fMLP (1 μ M) in monocytes or neutrophils was then determined. In these experiments it was observed that T21/DP107 did not desensitize the Ca^{++} flux in monocytes or neutrophils induced by chemokines such as MCP-1, RANTES, MCP-3, MIP-1 α , IL-8 and SDF-1. Therefore, T21/DP107 does not share a receptor with any of these chemokines. However, high concentrations ($\geq 1 \mu\text{M}$) of the bacterial chemotactic N-formylated peptide fMLP had a partial desensitizing effect on T21/DP107-induced Ca^{++} mobilization in both monocytes and neutrophils. In contrast, T21/DP107 did not significantly desensitize the effect of fMLP. These results clearly established that T21/DP107 was interacting with a formyl peptide receptor and this interaction induced Ca^{++} mobilization.

Since fMLP was known to induce Ca^{++} mobilization in phagocytes through at least two seven transmembrane, G-protein-coupled receptors, both members of the FPR class (e.g., FPR and FPRL1), we tested the effect of T21/DP107 on FPR and FPRL1 expressing human cells that, prior to transfection with a nucleic acid encoding the receptors, were not responsive to fMLP stimulation. (Prossnitz and Ye, *Pharmacol. Ther.* 74: 73 (1997); Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996); and Gao and M. Murphy, *J. Biol. Chem.* 268: 25395 (1993)). Over a wide range of concentrations, fMLP induced Ca^{++} mobilization in FPR-transfected rat basophil leukemia cell line (ETFR cells), with a minimal effective dose being at low pM concentration range. (FIGURE 8A). In contrast, the minimal effective concentration for fMLP to induce Ca^{++} mobilization in FPRL1 transfected cells (FPRL1/293 cells) was at low μM range. (FIGURE 8D). The synthetic T21/DP107 also induced Ca^{++} mobilization in cells transfected with either of these receptors. (FIGURES 8B and 8E). However, the minimal effective dose for T21/DP107 to activate FPRL1 was at nM range as compared with low μM range on FPR, demonstrating that T21/DP107 activates FPRL1 with higher efficacy.

5 A comparison of the interaction of T21/DP107 and fMLP on the two receptors was next performed. In FPR expressing cells, a 10^{-10} fMLP concentration versus a 10^{-5} concentration of T21/DP107 were required to induce a change in the ratio of 2 at 340/380 nm wavelength fluorescence; whereas in FPRL1/293 cells, a 5×10^{-5} fMLP concentration versus a 5×10^{-7} T21/DP107 concentration were required to induce a change in the ratio of 0.6. These results established that T21/DP107 was a more potent agonist for FPRL1 than fMLP. This finding was further supported by results of cross-desensitization of Ca^{++} flux between T21/DP107 and fMLP in both receptor transfectants. Although sequential stimulation of the cells expressing FPR or FPRL1 with T21/DP107 and fMLP resulted in bidirectional desensitization, a 1000-fold excess of fMLP was required to desensitize the effect of T21/DP107 in FPRL1/293 cells. (FIGURES 8C1, 8C2, 8F1, and 8F2). Conversely, a much higher concentration of T21/DP107 was necessary to completely abolish the fMLP response of cells expressing FPR. In control experiments, T21/DP107 and fMLP did not induce any Ca^{++} mobilization in parental or mock transfected rat basophil cell line and HEK 293 cells. These results provide more evidence that FPR and FPRL1 are differentially activated by fMLP and T21/DP107.

20 The chemotactic response of cells transfected with with a nucleic acid encoding FPR or FPRL1 was tested as another sensitive parameter to assess the receptor targets of T21/DP107. (Gong et al., *J. Biol. Chem.* 273: 4289 (1998); Gong et al., *J. Biol. Chem.* 272: 11682 (1997); and Ben-Baruch et al., *J. Biol. Chem.* 270: 22123 (1995)). Accordingly, different concentrations of T21/DP107 were placed in the lower wells of a chemotaxis chamber and a cell suspension was placed in the upper wells. The upper and lower wells were separated by polycarbonate filters precoated with mouse collagen type I. After incubation, the cells that migrated across the filters were stained and counted. FPRL1/293 cells showed a marked migratory response to T21/DP107 when compared to FPRL1/293 cells contacted with medium alone. The CI (chemotaxis index), which represents the fold increase of leukocyte migration in response to T21/DP107 over control medium, was also determined. FIGURE 9A shows that 30 FPRL1/293 cells migrated in response to stimulation with T21/DP107 with an EC50 of

50 nM, but these cells failed to migrate in response to a wide range of concentrations of fMLP. In contrast, ETFR cells were induced to migrate by fMLP at nM range concentrations, but much higher concentrations of T21/DP107 were required to induce the migration of the same cells. (FIGURE 9B). These chemotaxis experiments prove that fMLP is only a partial agonist for FPRL1 since it did not induce FPRL1 expressing cells to migrate. T21/DP107, on the other hand is an efficient agonist on both FPR and FPRL1, although the efficacy for FPR expressing cells was much lower than for FPRL1 expressing cells. In the following, we discuss in greater detail our experiments and findings that prove that T20/DP178 and T21/DP107 modulate an inflammatory response.

T20/DP178 and T21/DP107 modulate an inflammatory response

The findings above demonstrate that different gp41 domains activate multiple chemoattractant receptors which are not used by HIV-1 as fusion cofactors but play an important role in the recruitment and activation of phagocytic cells thus promoting host inflammatory and innate immune responses. (Dimitrov and Broder, *HIV and Membrane Receptors*, HIV and membrane fusion. Medical Intelligence Unit, Landes Bioscience, Austin, TX (1997); Berger, *AIDS* 11, Suppl A: S3 (1997); Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy and McDermott, *J. Biol. Chem.* 266: 12560 (1991); Murphy, *Annu. Rev. Immuno.* 12: 593 (1994); Murphy, *The N-formyl peptide chemotactic receptors*, Chemoattractant ligands and their receptors. CRC Press, Boca Raton, p. 269 (1996); and Gao et al., *J. Exp. Med.* 180: 2191 (1994)). Notably, the experiments above provide novel evidence that HIV-1 envelope gp41 contains domains that interact with a classical non-chemokine chemoattractant receptor on host phagocytes. Although envelope gp41 mediates viral fusion, regions of this protein T20/DP178 and T21/DP107 also interact with FPR members, activate phagocytic cells, induce a Ca^{++} flux, induce cell migration, and thereby up-regulate an inflammatory response. Additionally, we have shown that fragments of T20/DP178 interact with FPR members and act as antagonists which prevent activation of phagocytic cells and induction of cell migration and, thereby, down-regulates an inflammatory response.

Further, we contemplate that fragments of T21/DP107 act as antagonists to bind phagocytic cells but not induce cellular signaling.

Leukocyte infiltration at the sites of inflammation *in vivo* is considered to be based on migration of cells toward a gradient of chemoattractant(s), either derived from microorganisms or the local tissue. The discovery of synthetic N-formyl oligopeptide chemoattractants for phagocytes represented a major advance in the study of leukocyte locomotion. (Schiffmann et al., *Proc. Natl. Acad. Sci. U.S.A.* 72: 1059 (1975)). Several natural N-formyl peptide chemoattractants, including the prototype fMLP, have since been purified from bacterial supernatants, providing evidence that they are biologically relevant ligands for FPR. Mitochondrial proteins are also N-formylated and are chemotactic for neutrophils bearing FPR, representing a possible source of endogenous agonist(s). (Carp, H., *J. Exp. Med.* 155: 264 (1982)). Although early studies indicated that the N-formyl group was essential for optimal agonist potency, more recent studies have shown that non-formylated peptides may also bind the FPR and activate phagocyte function. (Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996); Freer et al., *Biochemistry* 21: 257 (1982); Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996); and Gao et al., *J. Exp. Med.* 180: 2191 (1994)).

The synthetic pentapeptide Met-Ile-Leu-Phe-Phe (SEQ ID NO:1), either N-formylated or N-acetylated, for example, is more potent than the parental prototype fMLP in the induction of Ca^{++} flux in human neutrophils. (Gao et al., *J. Exp. Med.* 180: 2191 (1994)). Amino terminal urea-substituted and carbonate-modified peptides are also potent agonists for the FPR. (Higgins et al., *J. Med. Chem.* 39: 1013 (1996); and Derian et al., *Biochemistry* 35: 1265 (1996)). In addition, altering the amino acid composition of these peptides can convert an agonist to an antagonist. In the experiments presented above, the non-N-formylated T20/DP178 does not bear any sequence identity to the reported FPR agonists yet showed potent FPR stimulating activity. Furthermore, the non-acetylated T20/DP178 was equally active as the acetylated form, proving that acetylation is not a requirement for T20/DP178 to stimulate FPR. Structural analysis of FPR revealed that the binding pocket of this

receptor is able to accommodate an amino terminal group larger than a formyl group. (Higgins et al., *J. Med. Chem.* 39: 1013 (1996); and Derian et al., *Biochemistry* 35: 1265 (1996)). A large binding pocket would enable many different ligands to bind to this receptor, and we have demonstrated that truncated mutants -- deletion of several amino acids from the N-terminus of T20/DP178 -- yielded antagonists of FPR, some of which still maintained significant anti-HIV-1 fusion efficacy. (Lawless et al., *Biochemistry* 35: 13697 (1996)). Thus, the spectrum of interaction between FPR and its agonists or antagonists is much broader than expected.

The binding of FPR by agonists, including fMLP, results in a cascade of G protein-mediated signaling events leading to phagocytic cell adhesion, chemotaxis, release of oxygen intermediates, enhanced phagocytosis and bacterial killing, as well as MAP kinase activation and gene transcription. (Krump et al., *J Biol Chem* 272:937 (1997); Prossnitz et al., *Pharmacol Ther* 74:73 (1997); Murphy, *Annu. Rev. Immuno.* 12: 593 (1994); and Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996)). Cell activation through FPR can also lead to desensitization of a subsequent cell response to other G-protein receptor ligands, including chemokines presumably by protein kinase mediated receptor phosphorylation. (Ali et al., *J. Biol. Chem.* 268: 24247 (1993); and Ali et al., *J. Biol. Chem.* 271: 3200 (1996)).

While fMLP is a high affinity agonist for FPR, it interacts with and induces Ca⁺⁺ flux in FPRL1 only at high concentrations. (Gao and M. Murphy, *J. Biol. Chem.* 268: 25395 (1993); Ye et al., *Biochem. Biophys. Res. Commun.* 184: 582 (1992); and Durstin et al., *Biochem. Biophys. Res. Commun.* 201: 174 (1994)). In our study, fMLP failed to induce significant migration of FPRL1/293 cells at a concentrations as high as 50 μ M (5 X 10⁻⁵ M), proving that fMLP is not a full agonist for FPRL1. In contrast, T21/DP107, although also activating both FPR and FPRL1 receptors, showed a much higher efficacy on FPRL1 and induces migration of FPRL1/293 cells at nM concentrations. Thus, compared to fMLP, T21/DP107 is a functionally more relevant agonist for FPRL1. It should be understood that T21/DP107 does not bear any significant sequence homology to fMLP. Although FPRL1 is mainly expressed in monocytes and neutrophils, cells other than phagocytes such as hepatocytes have also been shown to express FPRL1. (Prossnitz and Ye, *Pharmacol. Ther.* 74: 73 (1997)).

Recently, the expression of this receptor has been reported to be highly inducible in epithelial cells by specific cytokines such as IL-13 and IFN- γ . (Gronert et al., *J. Exp. Med.* 187: 1285 (1998)). Therefore, FPRL1 may play an important role in inflammatory and immunological responses in many different types of human cells.

5 In addition to peptide and protein agonists, a lipid metabolite lipoxin A4 (LXA4) has been reported to be a high affinity ligand and potent agonist for FPRL1 (also termed LXA4R). (Fiore et al., *J. Exp. Med.* 180: 253 (1994)). LXA4 is an eicosanoid generated during a number of host reactions such as inflammation, thrombosis and atherosclerosis, and was initially discovered as an inhibitor of immune
10 responses. (Reviewed in Samuelsson et al., *Science*. 237: 1171 (1987)). LXA4 was subsequently reported to inhibit neutrophil chemotaxis and transepithelial migration induced by chemotactic agents (Colgan et al., *J. Clin. Invest.* 92: 75 (1993) and Lee et al., *Biochem. Biophys. Res. Commun.* 180: 1416 (1991)). LXA4 bound to CHO cells transfected with FPRL1 increased GTPase activity and the release of esterified
15 arachidonate. (Fiore et al., *J. Exp. Med.* 180: 253 (1994)). Thus, LXA4 has been proposed to be an endogenously produced ligand for FPRL1. (Fiore et al., *J. Exp. Med.* 180: 253 (1994) and Takano et al., *J. Exp. Med.* 185: 1693 (1997)). Although LXA4 has not been documented to induce Ca^{++} mobilization in neutrophils or FPRL1 transfected cells, it was reported to induce Ca^{++} flux and chemotaxis in monocytes.
20 (Fiore et al., *J. Exp. Med.* 180: 253 (1994); Romano et al., *J. Immunol.* 157: 2149 (1994); and Maddox et al., *J. Biol. Chem.* 272: 6972 (1997)). In our experiments, however, we did not detect significant induction of Ca^{++} flux or chemotaxis in FPRL1/293 cells using commercially available LXA4 (Biomol, Plymouth Meeting, PA), nor did we observe inhibition of T21/DP107 signaling using LXA4 in either
25 phagocytes or FPRL1/293 cells.

 Although the signal transduction pathways mediated by FPRL1 has not been extensively studied, the high level of homology to FPR, sensitivity to pertussis toxin, and mediation of potent phagocyte migration and activation by its agonists provides substantial evidence that FPRL1 and FPR share many signal transduction steps
30 following activation. The binding of FPR by agonists results in a G protein-mediated signaling cascade leading to cell adhesion, chemotaxis, release of oxygen intermediates, enhanced phagocytosis and bacterial killing, as well as MAP kinase activation leading

to gene transcription. (Prossnitz and Ye, *Pharmacol. Ther.* 74: 73 (1997); Murphy, *The N-formyl peptide chemotactic receptors, Chemoattractant ligands and their receptors*. CRC Press, Boca Raton, p. 269 (1996)). Activation by fMLP can also lead to heterologous desensitization of the subsequent cell response to other G-protein receptor ligands including chemokines. (Ali et al., *J. Biol. Chem.* 268: 24247 (1993); and Ali et al., *J. Biol. Chem.* 268: 24247 (1993)). We contemplate that activation of FPRL1 also activates signaling events that cause desensitization of other G-protein coupled chemotactic receptors.

It has been reported that gp41 antigen could be detected in brain tissues of AIDS dementia (Adamson et. al., *Science* 274: 1917 (1996)), and antibodies recognizing various epitopes of gp41 appear at early stages of HIV-1 infection. (Nara et al., *FASEB J.* 5: 2437 (1991)). In fact, we found that both synthetic T21/DP107 and T20/DP178 epitopes of gp41 were recognized by sera from AIDS patients by immuno-blotting proving that gp41 and its epitopes are accessible to host cells including antigen presenting cells. Therefore, although the receptors for FPR members are not used by HIV-1 for fusion, we contemplate that they participate in the regulation of host innate immune and inflammatory responses seen in AIDS patients characterized by an initial stimulation of immune system in the early stage of the disease followed by progressive immunosuppression.

In the discussion below, we describe several methods of molecular modeling and rational drug design for the identification of homologous ligands which interact with FPR members and thereby modulate an inflammatory response.

Methods of rational drug design

In some embodiments, search programs are employed to compare regions of T20/DP178, T21/DP107, and fragments thereof which modulate an inflammatory response with other molecules, such as peptides, peptidomimetics, and chemicals, so that therapeutic interactions of new molecules (e.g., ligands for FPR members) can be predicted. (Schneider, *Genetic Engineering News* December: page 20 (1998), Tempczyk et al., *Molecular Simulations Inc. Solutions* April (1997) and Butenhof, *Molecular Simulations Inc. Case Notes* (August 1998)). This process is referred to as "rational drug design". One goal of rational drug design is to produce structural or functional analogs

of biologically active polypeptides of interest or of small molecules with which they interact (e.g., agonists, antagonists, null compounds) in order to fashion drugs which are, for example, more or less potent forms of the ligand. (See, e.g., Hodgson, *Bio. Technology* 9:19-21 (1991)). An example of rational drug design is the development of HIV protease inhibitors. (Erickson et al., *Science* 249:527-533 (1990)).

By starting with the sequence or protein models of T20/DP178, T21/DP107, and/or fragments thereof ligands having two-dimensional and/or three-dimensional homology can be rapidly identified. In one approach, a percent sequence identity can be determined by standard methods that are commonly used to compare the similarity and position of the amino acid of two polypeptides. Using a computer program such as BLAST or FASTA, two polypeptides are aligned for optimal matching of their respective amino acids (either along the full length of one or both sequences, or along a predetermined portion of one or both sequences). Such programs provide "default" opening penalty and a "default" gap penalty, and a scoring matrix such as PAM 250 (a standard scoring matrix; see Dayhoff et al., in: *Atlas of Protein Sequence and Structure*, Vol. 5, Supp. 3 (1978)) can be used in conjunction with the computer program. The percent identity can then be calculated as:

$$\frac{\text{total number of identical matches}}{[\text{length of the longer sequence within the matched span} + \text{number of gaps introduced into the longer sequence in order to align the two sequences}]} \times 100$$

Accordingly, the protein sequence corresponding to T20/DP178 and T21/DP107 is compared to known sequences on a protein basis. Protein sequences corresponding to T20/DP178 and T21/DP107 are compared, for example, to known amino acid sequences found in Swissprot release 35, PIR release 53 and Genpept release 108 public databases using BLASTP with the parameter W=8 and allowing a maximum of 10 matches. In addition, the protein sequences encoding T20/DP178 and T21/DP107 are compared to publicly known amino acid sequences of Swissprot using BLASTX with the parameter E=0.001. The candidate ligands desirably have at least 50% homology and preferably have 60% or 70% or 80% or 90% or greater homology to T20/DP178 and T21/DP107. The candidate ligands may have the following degrees of homology to T20/DP178 and T21/DP107, for example: 50%, 51%, 52%, 53%, 54%, 55%, 56%,

57%, 58%, 59%, 60%, 61%, 62%, 63%, 64%, 65%, 66%, 67%, 68%, 69%, 70%, 71%, 72%, 73%, 74%, 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, and 99%. The candidate ligands having greater than or equal to 50% homology are identified and are subsequently examined using the functional assays described herein. Candidate ligands which can interact with an FPR member and thereby modulate an inflammatory response are, thus, identified.

Additionally, a search program is used to compare the three-dimensional structure of T20/DP178 and T21/DP107 with other known sequences so as to identify candidate ligands which can interact with an FPR member and thereby modulate an inflammatory response. In the past, the three-dimensional structure of proteins has been determined in a number of ways. Perhaps the best known way of determining protein structure involves the use of x-ray crystallography. A general review of this technique can be found in Van Holde, K.E. Physical Biochemistry, Prentice-Hall, N.J. pp. 221-239 (1971). Using this technique, it is possible to elucidate three-dimensional structure with good precision. Additionally, protein structure may be determined through the use of techniques of neutron diffraction, or by nuclear magnetic resonance (NMR). (See, e.g., Moore, W.J., Physical Chemistry, 4th Edition, Prentice-Hall, N.J. (1972)).

Alternatively, the protein model embodiments of the present invention are constructed using computer-based protein modeling techniques. By one approach, the protein folding problem is solved by finding target sequences that are most compatible with profiles representing the structural environments of the residues in known three-dimensional protein structures. (See, e.g., Eisenberg et al., U.S. Patent No. 5,436,850 issued July 25, 1995). In another technique, the known three-dimensional structures of proteins in a given family are superimposed to define the structurally conserved regions in that family. This protein modeling technique also uses the known three-dimensional structure of a homologous protein to approximate the structure of a ligand of interest. (See e.g., Srinivasan, et al., U.S. Patent No. 5,557,535 issued September 17, 1996). Conventional homology modeling techniques have been used routinely to build models of proteases and antibodies. (Sowdhamini et al., Protein Engineering 10:207, 215 (1997)). Comparative approaches can also be used to develop three-dimensional protein models when the protein of interest has poor sequence identity to template

proteins. In some cases, proteins fold into similar three-dimensional structures despite having very weak sequence identities. For example, the three-dimensional structures of a number of helical cytokines fold in similar three-dimensional topology in spite of weak sequence homology.

5 The recent development of threading methods and "fuzzy" approaches now enables the identification of likely folding patterns and functional protein domains in a number of situations where the structural relatedness between target and template(s) is not detectable at the sequence level. By one method, fold recognition is performed using Multiple Sequence Threading (MST) and structural equivalences are deduced
10 from the threading output using the distance geometry program DRAGON which constructs a low resolution model. A full-atom representation is then constructed using a molecular modeling package such as QUANTA.

 According to this 3-step approach, candidate templates are first identified by using the novel fold recognition algorithm MST, which is capable of performing
15 simultaneous threading of multiple aligned sequences onto one or more 3-D structures. In a second step, the structural equivalences obtained from the MST output are converted into interresidue distance restraints and fed into the distance geometry program DRAGON, together with auxiliary information obtained from secondary structure predictions. The program combines the restraints in an unbiased manner and
20 rapidly generates a large number of low resolution model confirmations. In a third step, these low resolution model confirmations are converted into full-atom models and subjected to energy minimization using the molecular modeling package QUANTA. (See e.g., Aszódi et al., Proteins:Structure, Function, and Genetics, Supplement 1:38-42 (1997)).

25 In one approach, a three-dimensional structure of a ligand of interest (e.g., T20/DP178, T21/DP107, and/or fragments thereof) is determined by x-ray crystallography, NMR, or neutron diffraction and computer modeling, as described above. Useful protein models of the ligand may also be gained by computer modeling alone. Combinatorial chemistry is then employed to design derivatives of the ligand of
30 interest based on the three-dimensional models. The chemoattraction, cell migration, Ca^{++} mobilization, and ligand binding competition assays, as well as, the immunohistochemistry and other assays described above (referred to collectively as

"FPR class characterization assays") are then performed on the derivative ligands and groups of ligands based on the potency of inflammatory response are identified and recorded on a computer readable media. Further cycles of modeling and FPR class characterization assays are employed to more narrowly define the parameters needed in a ligand which elicits a desired response.

In addition, a ligand peptide of interest (e.g., T20/DP178, T21/DP107, and fragments thereof) can be analyzed by an alanine scan (Wells, Methods in Enzymol. 202:390-411 (1991)). In this technique, an amino acid residue is replaced by alanine, and its affect on the peptide's activity is measured by functional assays, such as the FPR class characterization assays described herein. Each of the amino acid residues of the peptide is analyzed in this manner and the regions important for a specific inflammatory response are identified. Subsequently, these functionally important regions are recorded on a computer readable medium, stored in a first database in a computer system, and a search program is employed to generate protein models of the functionally important regions. Once protein models of the functionally important regions have been generated, a second database comprising one or more libraries having peptides, chemicals, peptidomimetics and other agents is accessed by a search program and individual agents are compared to the protein models to identify agents which comprise homologous regions or domains which resemble the identified functionally important regions. Agents identified by the approach above are then tested in the FPR class characterization assays and are used to construct multimeric agents and/or are incorporated into pharmaceuticals, as detailed below.

In another embodiment, computer modeling and the sequence-to-structure-to-function paradigm is exploited to identify more ligands which modulate an inflammatory response through an FPR member. By this approach, first the structure of a protein ligand having a known response in a FPR class characterization assay (e.g., T20/DP178, T21/DP107, and fragments thereof) is determined from its sequence using a threading algorithm, which aligns the sequence to the best matching structure in a structural database. Next, the protein's active site (i.e., the site important for a desired response in the FPR class characterization assay) is identified and a "fuzzy functional form" (FFF) -- a three-dimensional descriptor of the active site of a protein -- is created.

(See e.g., Fetrow et al., *J. Mol. Biol.* 282:703-711 (1998) and Fetrow and Skolnick, *J. Mol. Biol.* 281: 949-968 (1998)).

The FFFs are built by iteratively superimposing the protein geometries from a series of functionally related proteins with known structures. The FFFs are not overly specific, however, and the degree to which the descriptors can be relaxed is explored. In essence, conserved and functionally important residues for a desired inflammatory response are identified and a set of geometric and conformational constraints for a specific function are defined in the form of a computer algorithm. The program then searches experimentally determined protein structures from a protein structural database for sets of residues that satisfy the specified constraints. In this manner, homologous three-dimensional structures can be compared and degrees (e.g., percentages of three-dimensional homology) can be ascertained.

By using this computational protocol, genome sequence data bases such as maintained by various organizations including: <http://www.tigr.org/tdb>; <http://www.genetics.wisc.edu>; <http://genome-www.stanford.edu/~ball>; <http://hiv-web.lanl.gov>; <http://www.ncbi.nlm.nih.gov>; <http://www.ebi.ac.uk>; <http://pasteur.fr/other/biology>; and <http://www-genome.wi.mit.edu>, can be rapidly screened for specific protein active sites and for identification of the residues at those active sites which resemble a desired ligand. Several other groups have developed databases of short sequence patterns or motifs designed to identify a given function or activity of a protein. These databases, notably Prosite (<http://expasy.hcuge.ch/sprot/prosite.html>); Blocks (<http://www.blocks.fhcrc.org>); and Prints (<http://www.biochem.ucl.ac.uk/bsm/dbbrowser/PRINTS/PRINTS.html>), use short stretches of sequence information to identify sequence patterns that are specific for a given function; thus they avoid the problems arising from the necessity of matching entire sequences. In this manner, new ligands are rationally selected for further identification by FPR class characterization assays, as described above. Rounds or cycles of functional assays on the molecules and derivatives thereof and further FFF refinement and database searching allows an investigator to more narrowly define classes of ligands which produce desirable inflammatory responses.

Many computer programs and databases may be used with embodiments of the invention to identify agents which modulate an inflammatory response. The following list

is intended not to limit the invention but to provide guidance to programs and databases which are useful with the approaches discussed above. The programs and databases which may be used include, but are not limited to: MacPattern (EMBL), DiscoveryBase (Molecular Applications Group), GeneMine (Molecular Applications Group), Look (Molecular Applications Group), MacLook (Molecular Applications Group), BLAST and BLAST2 (NCBI), BLASTN and BLASTX (Altschul et al, *J. Mol. Biol.* 215: 403 (1990)), FASTA (Pearson and Lipman, *Proc. Natl. Acad. Sci. USA*, 85: 2444 (1988)), Catalyst (Molecular Simulations Inc.), Catalyst/SHAPE (Molecular Simulations Inc.), Cerius².DBAccess (Molecular Simulations Inc.), HypoGen (Molecular Simulations Inc.), Insight II, (Molecular Simulations Inc.), Discover (Molecular Simulations Inc.), CHARMM (Molecular Simulations Inc.), Felix (Molecular Simulations Inc.), DelPhi, (Molecular Simulations Inc.), QuanteMM, (Molecular Simulations Inc.), Homology (Molecular Simulations Inc.), Modeler (Molecular Simulations Inc.), Modeller 4 (Sali and Blundell *J. Mol. Biol.* 234:217-241 (1997)), ISIS (Molecular Simulations Inc.), Quanta/Protein Design (Molecular Simulations Inc.), WebLab (Molecular Simulations Inc.), WebLab Diversity Explorer (Molecular Simulations Inc.), Gene Explorer (Molecular Simulations Inc.), SeqFold (Molecular Simulations Inc.), the EMBL/Swissprotein database, the MDL Available Chemicals Directory database, the MDL Drug Data Report data base, the Comprehensive Medicinal Chemistry database, Derwent's World Drug Index database, and the BioByteMasterFile database. Many other programs and data bases would be apparent to one of skill in the art given the present disclosure.

Libraries of information on ligands with their corresponding inflammatory response can be generated by performing the rational drug design approaches above in conjunction with FPR class characterization assays. A record of the results for each ligand is generated and groups of ligands are identified and stored on a computer readable media. Databases of this information would be valuable to investigators and clinicians for selecting the type of ligand-based pharmaceutical to treat or elicit a particular inflammatory response. Preferable libraries are created by performing the assays above on the ligands T20/DP178, T21/DP107, and fragments thereof.

In several embodiments of the present invention, T20/DP178, T21/DP107, and fragments thereof are incorporated into biotechnological tools and pharmaceuticals for therapeutic and prophylactic application. Preferably, the peptides T20/DP178,

T21/DP107, and fragments thereof correspond to the sequences listed in Example 1 and Example 2. The peptides T20/DP178, T21/DP107, and fragments thereof can be longer or shorter than the peptides listed in Example 1 and 2, however, and desirable peptides are between three amino acids and 100 amino acids in length and have at least some portion of the sequence which corresponds to the peptides T20/DP178 and T21/DP107. Additionally, peptidomimetics which resemble the peptides T20/DP178, T21/DP107, and fragments thereof or peptides of between three and 100 amino acids having sequence which corresponds to the peptides T20/DP178 and T21/DP107, are embodiments of the present invention. For example, an oligopeptide for use in aspects of the present invention may have three amino acids, four amino acids, five amino acids, six amino acids, seven amino acids, eight, nine, ten, eleven, twelve, thirteen, fourteen, fifteen, sixteen, seventeen, eighteen, nineteen, twenty, twenty-one, twenty-two, twenty-three, twenty-four, twenty-five, twenty-six, twenty-seven, twenty-eight, twenty-nine, thirty, thirty-one, thirty-two, thirty-three, thirty-four, thirty-five, thirty-six, thirty-seven, thirty-eight, thirty nine, or forty or fifty or sixty or seventy or eighty or ninety or one-hundred amino acids. Similarly, peptidomimetics of the present invention may have structures that resemble three amino acids, four amino acids, five amino acids, six amino acids, seven amino acids, eight, nine, ten, eleven, twelve, thirteen, fourteen, fifteen, sixteen, seventeen, eighteen, nineteen, twenty, twenty-one, twenty-two, twenty-three, twenty-four, twenty-five, twenty-six, twenty-seven, twenty-eight, twenty-nine, thirty, thirty-one, thirty-two, thirty-three, thirty-four, thirty-five, thirty-six, thirty-seven, thirty-eight, thirty nine, or forty or fifty or sixty or seventy or eighty or ninety or one-hundred amino acids.

Peptides for use in aspects of the present invention may also be modified, e.g., the peptides may have substituents not normally found on a peptide or the peptides may have substituents that are normally found on the peptide but are incorporated at regions of the peptide that are not normal. The peptides for use in aspects of the present invention may be acetylated, acylated, or aminated, for example. Substituents which may be included on the peptide so as to modify it include, but are not limited to, H, alkyl, aryl, alkenyl, alkynyl, aromatic, ether, ester, unsubstituted or substituted amine, amide, halogen or unsubstituted or substituted sulfonyl or a 5 or 6 member aliphatic or aromatic ring. As used throughout this disclosure, the term "peptide agent" refers to a

modified or unmodified peptide and a chemical or a peptidomimetic which structurally (three-dimensionally or two-dimensionally) resembles a modified or unmodified T20/DP178, T21/DP107, and/or a fragment thereof. Peptide agents include, but are not limited to, ligands identified by the methods of rational drug design detailed above by virtue of structural relatedness to T20/DP178, T21/DP107, or a fragment of T20/DP178, T21/DP107, or a peptidomimetic which resembles T20/DP178, T21/DP107, and a fragment thereof.

The peptides T20/DP178, T21/DP107, and fragments or derivatives thereof, include but are not limited to, those containing as a primary amino acid sequence all or part of the amino acid sequence substantially as depicted in Examples 1 and 2 including altered sequences in which functionally equivalent amino acid residues are substituted for residues within the sequence resulting in a silent change. Accordingly, one or more amino acid residues within the sequence can be substituted by another amino acid of a similar polarity which acts as a functional equivalent, resulting in a silent alteration. Substitutes for an amino acid within the sequence may be selected from other members of the class to which the amino acid belongs. For example, the non-polar (hydrophobic) amino acids include alanine, leucine, isoleucine, valine, proline, phenylalanine, tryptophan, and methionine. The uncharged polar neutral amino acids include glycine, serine, threonine, cysteine, tyrosine, asparagine and glutamine. The positively charged (basic) amino acids include arginine, lysine, and histidine. The negatively charged (acidic) amino acids include aspartic acid and glutamic acid. The aromatic amino acids include phenylalanine, tryptophan, and tyrosine. In other aspects of the invention, T20/DP178, T21/DP107, and fragments or derivatives thereof, which are differentially modified during or after translation, e.g., by phosphorylation, glycosylation, cross-linking, acylation, proteolytic cleavage, linkage to an antibody molecule, membrane molecule, or other ligand, are contemplated. (Ferguson et al., *Ann. Rev. Biochem.* 57:285-320 (1988)).

10 The invention includes T20/DP178 and fragments having at least one acidic amino acid substitution selected from the group consisting of:

E10Z, E11Z, E17Z, E20Z, E22Z E25Z, D27Z, where Z is an acidic amino acid.

The invention includes T20/DP178 and fragments having at least one basic amino acid substitution selected from the group consisting of:

H6B, K18B, K28B, where B is a basic amino acid.

15 The invention includes T20/DP178 and fragments having at least one non-polar amino acid substitution selected from the group consisting of:

L4J, I5J L8J, I9J, L23J, L24J, L26J, W29J, A30J, L32J, W33J, W35J, F36J, where J is a non-polar amino acid.

20 The invention includes T20/DP178 and fragments having at least one uncharged polar amino acid substitution selected from the group consisting of:

Y1U, T2U, S3U, S7U, S12U, Q13U, N14U, Q15U, Q16U, N19U, Q21U, S31U, N34U, where U is an uncharged polar amino acid.

The invention includes T20/DP178 and fragments having at least one aromatic amino acid substitution selected from the group consisting of:

25 Y1X, T2X, F36X, where X is an aromatic amino acid.

The invention includes T21/DP107 and fragments having at least one acidic amino acid substitution selected from the group consisting of:

E8Z, E32Z, D37Z, where Z is an acidic amino acid.

30 The invention includes T21/DP107 and fragments having at least one basic amino acid substitution selected from the group consisting of:

R5B, H12B, K22B, R27B, R33B, K36B, where B is a basic amino acid.

The invention includes T21/DP107 and fragments having at least one non-polar amino acid substitution selected from the group consisting of:

L3J, L4J, A6J, I7J, A9J, L13J, L14J, L16J, V18J, W19J, I21J, L24J, A26J, I28J, L29J, A30J, V31J, L35J, where J is a non-polar amino acid.

5 The invention includes T21/DP107 and fragments having at least one uncharged polar amino acid substitution selected from the group consisting of:

N1U, N2U, Q10U, Q11U, Q15U, T17U, G20U, Q23U, Q25U, Y34U, Q38U, where U is an uncharged polar amino acid.

10 The invention includes T21/DP107 and fragments having at least one aromatic amino acid substitution selected from the group consisting of:

T17X, Y34X, where X is an aromatic amino acid.

15 In many embodiments, we use isolated or purified T20/DP178, T21/DP107, or fragments thereof. The term "isolated" requires that a material be removed from its original environment (e.g., the natural environment if it is naturally occurring). For example, a naturally occurring polynucleotide or polypeptide present in a living cell is not isolated, but the same polynucleotide or polypeptide, separated from some or all of the coexisting materials in the natural system, is isolated.

20 The term "purified" does not require absolute purity; rather it is intended as a relative definition, with reference to the purity of the material in its natural state. Purification of natural material to at least one order of magnitude, preferably two or three magnitudes, and more preferably four or five orders of magnitude is expressly contemplated.

25 The term "enriched" means that the concentration of the material is at least about 2, 5, 10, 100, or 1000 times its natural concentration (for example), advantageously 0.01% by weight. Enriched preparations of about 0.5%, 1%, 5%, 10%, and 20% by weight are also contemplated.

30 In the disclosure below, we teach the preparation of multimeric supports having peptide agents which interact with an FPR member and thereby modulate an inflammatory response. These multimeric supports have many uses including, but not limited to, the manufacture of biotechnological tools and components for pharmaceuticals, therapeutic and prophylactic agents.

Preparation of multimeric supports and multimerized ligands

In order to be useful as a biotechnological tool or a component to a prophylactic or therapeutic agent, it is desirable to provide the peptide agent in such a form or in such a way that a sufficient affinity for an FPR member is obtained. While a natural monomeric peptide agent (e.g., T20/DP178, T21/DP107, and fragments thereof appearing as discrete units of the peptide each carrying only one binding epitope) is sufficient to interact with an FPR member and thereby modulate an inflammatory response, synthetic ligands or multimeric ligands (e.g., T20/DP178, T21/DP107, and fragments thereof appearing as multiple units of the peptide agent with several binding epitopes) may have far greater ability to interact with an FPR member and thereby modulate an inflammatory response. It should be noted that the term "multimeric" is meant to refer to the presence of more than one unit of a ligand, for example several individual molecules of T20/DP178, T21/DP107, or fragments thereof, as distinguished from the term "multimerized" which refers to the presence of more than one ligand joined as a single discrete unit, for example several molecules of T20/DP178, T21/DP107, or fragments thereof joined in tandem.

A multimeric agent (synthetic or natural) which modulates an immune response through an FPR member may be obtained by coupling a T20/DP178, T21/DP107, a fragment of T20/DP178, T21/DP107, or a peptidomimetic which resembles T20/DP178, T21/DP107, or a fragment thereof to a macromolecular support. A "support" may also be termed a carrier, a resin or any macromolecular structure used to attach or immobilize a peptide agent. Solid supports include, but are not limited to, the walls of wells of a reaction tray, test tubes, polystyrene beads, magnetic beads, nitrocellulose strips, membranes, microparticles such as latex particles, sheep (or other animal) red blood cells, artificial cells and others. The macromolecular support may have a hydrophobic surface which interacts with a portion of the peptide agent by hydrophobic non-covalent interaction. The hydrophobic surface of the support may also be a polymer such as plastic or any other polymer in which hydrophobic groups have been linked such as polystyrene, polyethylene or polyvinyl. Alternatively, the peptide agent can be covalently bound to carriers including proteins and oligo/polysaccharides (e.g. cellulose, starch, glycogen, chitosane or aminated sepharose).

In these later embodiments, a reactive group on the peptide agent, such as a hydroxy or an amino group, may be used to join to a reactive group on the carrier so as to create the covalent bond. The support may also have a charged surface which interacts with the peptide agent. Additionally, the support may have other reactive groups which can be chemically activated so as to attach a peptide agent. For example, cyanogen bromide activated matrices, epoxy activated matrices, thio and thiopropyl gels, nitrophenyl chloroformate and N-hydroxy succinimide chloroformate linkages, and oxirane acrylic supports are common in the art. (Sigma).

The support may also comprise an inorganic carrier such as silicon oxide material (e.g. silica gel, zeolite, diatomaceous earth or aminated glass) to which the peptide agent is covalently linked through a hydroxy, carboxy or amino group and a reactive group on the carrier. Furthermore, in some embodiments, a liposome or lipid bilayer (natural or synthetic) is contemplated as a support and peptide agents are attached to the membrane surface or are incorporated into the membrane by techniques in liposome engineering. By one approach, liposome multimeric supports comprise a peptide agent that is exposed on the surface of the bilayer and a second domain which anchors the peptide agent to the lipid bilayer. The anchor may be constructed of hydrophobic amino acid residues, resembling known transmembrane domains, or may comprise ceramides that are attached to the first domain by conventional techniques.

Carriers for use in the body, (i.e. for prophylactic or therapeutic applications) are desirably physiological, non-toxic and preferably, non-immunoresponsive. Suitable carriers for use in the body include poly-L-lysine, poly-D, L-alanine, liposomes, and Chromosorb[®] (Johns-Manville Products, Denver Co.). Ligand conjugated Chromosorb[®] (Synsorb-Pk) has been tested in humans for the prevention of hemolytic-uremic syndrome and was reported as not presenting adverse reactions. (*Armstrong et al. J. Infectious Diseases 171:1042-1045 (1995)*). For some embodiments, a "naked" carrier (i.e., lacking an attached peptide agent) which has the capacity to attach a peptide agent in the body of a subject is administered. By this approach, a "prodrug-type" therapy is envisioned in which the naked carrier is administered separately from the peptide agent and, once both are in the body of the subject, the carrier and the peptide agent are assembled into a multimeric complex.

The insertion of linkers, such as λ linkers, of an appropriate length between the peptide agent and the support are also contemplated so as to encourage greater flexibility of the peptide agent and thereby overcome any steric hindrance which may be presented by the support. The determination of an appropriate length of linker which allows for an optimal desired inflammatory response or lack thereof, can be determined by screening the peptide agents with varying linkers in the assays detailed in the present disclosure.

A composite support comprising more than one type of peptide agent is also envisioned. A "composite support" may be a carrier, a resin, or any macromolecular structure used to attach or immobilize two or more different peptide agents which modulate an inflammatory response through an FPR member. In some embodiments, a liposome or lipid bilayer (natural or synthetic) is contemplated for use in constructing a composite support and peptide agents are attached to the membrane surface or are incorporated into the membrane using techniques in liposome engineering.

As above, the insertion of linkers, such as λ linkers, of an appropriate length between the peptide agent and the support is also contemplated so as to encourage greater flexibility in the molecule and thereby overcome any steric hindrance which may occur. The determination of an appropriate length of linker which allows for optimal binding to an FPR member, can be determined by screening the ligands with varying linkers in the assays detailed in the present disclosure.

In other embodiments of the present invention, the multimeric and composite supports discussed above may have attached multimerized ligands so as to create a "multimerized-multimeric support" and a "multimerized-composite support", respectively. A multimerized ligand may, for example, be obtained by coupling two or more peptide agents in tandem using conventional techniques in molecular biology. The multimerized form of the ligand may be advantageous for many applications because of the ability to obtain an agent with a better ability to bind to an FPR member and, thereby, modulate an inflammatory response. We further contemplate that the incorporation of linkers or spacers, such as flexible λ linkers, between the individual domains which make-up the multimerized agent may be advantageous. The insertion of λ linkers of an appropriate length between protein binding domains, for example, may encourage greater flexibility in the molecule and can overcome steric hindrance.

Similarly, the insertion of linkers between the multimerized ligand and the support may encourage greater flexibility and limit steric hindrance presented by the support. The determination of an appropriate length of linker which allows for optimal binding to a formyl peptide receptor and, thereby, modulates an inflammatory response, can be determined by screening the ligands with varying linkers in the assays detailed in this disclosure.

In preferable embodiments, the various types of supports discussed above are created using T20/DP178, T21/DP107, a fragment of T20/DP178, T21/DP107, or a peptidomimetic which resembles T20/DP178, T21/DP107, or a fragment thereof. The multimeric supports, composite supports, multimerized-multimeric supports, or multimerized-composite supports, collectively referred to as "support-bound agents", are also preferably constructed using T20/DP178, T21/DP107, a fragment of T20/DP178, T21/DP107, or a peptidomimetic which resembles T20/DP178, T21/DP107, or a fragment thereof.

In the discussion below, the present inventor describes several embodiments of the invention which have therapeutic and/ or prophylactic application.

Therapeutic and prophylactic applications

In the therapeutic and prophylactic embodiments of the present invention, the peptide agents identified as upregulating or downregulating an inflammatory response are incorporated into a pharmaceutical product and are administered to a subject in need. The monomeric and multimeric peptide agents of the invention are suitable for treatment of subjects either as a preventive measure to avoid an inflammatory response or as a therapeutic to treat subjects in need of an anti-inflammatory agent. Additionally, in some prophylactic and/or therapeutic applications, the monomeric and multimeric agents are administered to elicit an inflammatory response.

One contemplated method of making a pharmaceutical involves the selection of a peptide agent which interacts with an FPR member, preferably T20/DP178, T21/DP107, a fragment of T20/DP178, T21/DP107, or a peptidomimetic which resembles T20/DP178, T21/DP107, or a fragment thereof, and incorporating the peptide agent into a pharmaceutical by conventional techniques. The pharmaceuticals of the present invention may be formulated with an adjuvant or may be free and desirable

embodiments provide the peptide agent in a support-bound form. Optionally, the peptide agent can be provided in an aggregated form as created, for example, by heating.

In another method of making a pharmaceutical, we envision incorporating a peptide agent selected for its ability to block, inhibit, or prevent an inflammatory response in the FPR class characterization assays described above. Accordingly, a peptide agent which interacts with an FPR member blocks, inhibits, or prevents an inflammatory response is identified and is incorporated into a pharmaceutical by conventional techniques. Preferable peptide agents include, but are not limited to fragments of T20/DP178, T21/DP107, or peptidomimetics which resemble fragments of T20/DP178 or T21/DP107. A novel class of anti-inflammatory agents which bind an FPR member with high avidity but fail to induce an inflammatory response are designed using approaches in rational drug design, described above, and known in the art. These pharmaceuticals are formulated in adjuvant or free and are provided in the form of a support-bound agent, as well. As above, an aggregated form of this embodiment may be created by heating the proteins and can administered to subjects in need.

The compounds of this invention can be employed in admixture with conventional excipients, i.e., pharmaceutically acceptable organic or inorganic carrier substances suitable for parenteral, enteral (e.g., oral) or topical application which do not deleteriously react with the active compounds. Suitable pharmaceutically acceptable carriers include but are not limited to water, salt solutions, alcohols, gum arabic, vegetable oils, benzyl alcohols, polyethylene glycols, gelatine, carbohydrates such as lactose, amylose or starch, magnesium stearate, talc, silicic acid, viscous paraffin, perfume oil, fatty acid monoglycerides and diglycerides, pentaerythritol fatty acid esters, hydroxy methylcellulose, polyvinyl pyrrolidone, etc. The pharmaceutical preparations can be sterilized and if desired mixed with auxiliary agents, e.g., lubricants, preservatives, stabilizers, wetting agents, emulsifiers, salts for influencing osmotic pressure, buffers, coloring, flavoring and/or aromatic substances and the like which do not deleteriously react with the active compounds. They can also be combined where desired with other active agents, e.g., vitamins. The ligands may also be administered in the form of a support-bound agent or in a pro-drug form which interacts with a support so as to create a support-bound agent in the body of the subject.

In another embodiment, therapeutic agents comprising the peptide agents of the disclosed invention are administered in conjunction with other therapeutic agents which modulate an inflammatory response. It is thus a preferred embodiment of the present invention that the peptide agents be given in combination with non-steroidal anti-inflammatory drugs (NSAID) such as aspirin, ketoprofen, flurbiprofen, ibuprofen, and naproxyn at doses and by methods known to those of skill in the art. Alternatively, it is desirable that the peptide agents be given in combination with agents which induce an inflammatory response such as vaccines, adjuvants, and histimine. Medicaments comprising the peptide agents of the present invention and conventional NSAIDs or conventional agents which induce an inflammatory response are also embodiments of the present invention.

The peptide agents can be administered alone or in combination with other peptides or with other NSAIDs or conventional agents which induce an inflammatory response and can be combined with physiologically acceptable carriers. Further, the manufacture of pharmaceuticals or therapeutic agents which deliver the peptide agent and/or a nucleic acid sequence encoding the peptide agent by several routes is another aspect of the invention. For example, and not by way of limitation, the use of DNA, RNA, and viral vectors having sequence encoding the peptide agent is contemplated. Nucleic acids encoding a desired peptide agent can be administered alone or in combination with peptide agents.

In the following disclosure, doses and methods of administration are provided.

Dosage and methods of administration

The effective dose and method of administration of a particular formulation of a peptide agent may vary based on the individual subject and the stage of the disease, as well as other factors known to those of skill in the art. Therapeutic efficacy and toxicity of such compounds can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., ED50 (the dose therapeutically effective in 50% of the population) and LD50 (the dose lethal to 50% of the population). The dose ratio of toxic to therapeutic effects is the therapeutic index, and it can be expressed as the ratio, LD50/ED50. Pharmaceutical compositions which exhibit large therapeutic indices are preferred. The data obtained from cell culture assays and animal studies is

used in formulating a range of dosage for human use. The dosage of such compounds lies preferably within a range of circulating concentrations that include the ED50 with little or no toxicity. The dosage varies within this range depending upon the dosage form employed, sensitivity of the patient, and the route of administration.

5 The exact dosage is chosen by the individual physician in view of the patient to be treated. Dosage and administration are adjusted to provide sufficient levels of the active moiety or to maintain the desired effect. Additional factors which may be taken into account include the severity of the disease state, age, weight and gender of the patient; diet, time and frequency of administration, drug combination(s), reaction
10 sensitivities, and tolerance/response to therapy. Long acting pharmaceutical compositions might be administered every 3 to 4 days, every week, or once every two weeks depending on half-life and clearance rate of the particular formulation.

 Normal dosage amounts may vary from 0.1 to 100,000 micrograms, up to a total dose of about 10 grams, depending upon the route of administration. Guidance as to
15 particular dosages and methods of delivery is provided in the literature. (See U.S. Pat. Nos. 4,657,760; 5,206,344; or 5,225,212.) More specifically, the dosage of the peptide agents of the present invention is one that provides sufficient peptide agent to attain a desirable effect including an up-regulation or a down regulation of an inflammatory response. A constant infusion of the peptide agent can also be provided so as to
20 maintain a stable concentration in the tissues as measured by blood levels.

 Routes of administration of the peptide agents include, but are not limited to, topical, transdermal, parenteral, gastrointestinal, transbronchial, and transalveolar. Topical administration is accomplished via a topically applied cream, gel, rinse, etc. containing a peptide agent. Transdermal administration is accomplished by application
25 of a cream, rinse, gel, etc. capable of allowing the peptide agent to penetrate the skin and enter the blood stream. Parenteral routes of administration include, but are not limited to, electrical or direct injection such as direct injection into a central venous line, intravenous, intramuscular, intraperitoneal or subcutaneous injection. Gastrointestinal routes of administration include, but are not limited to, ingestion and rectal.
30 Transbronchial and transalveolar routes of administration include, but are not limited to, inhalation, either via the mouth or intranasally.

100505-1004
TOP SECRET

Compositions of peptide agent-containing compounds suitable for topical application include, but not limited to, physiologically acceptable implants, ointments, creams, rinses, and gels. Any liquid, gel, or solid, pharmaceutically acceptable base in which the peptide agents are at least minimally soluble is suitable for topical use in aspects of the present invention. For topical application, there are also employed as non-sprayable forms, viscous to semi-solid or solid forms comprising a carrier compatible with topical application and having a dynamic viscosity preferably greater than water. Suitable formulations include but are not limited to solutions, suspensions, emulsions, creams, ointments, powders, liniments, salves, aerosols, etc., which are, if desired, sterilized or mixed with auxiliary agents, e.g., preservatives, stabilizers, wetting agents, buffers or salts for influencing osmotic pressure, etc. For topical application, also suitable are sprayable aerosol preparations wherein the active ingredient, preferably in combination with a solid or liquid inert carrier material, is packaged in a squeeze bottle or in admixture with a pressurized volatile, normally gaseous propellant, e.g., a freon.

Compositions of the peptide agents suitable for transdermal administration include, but are not limited to, pharmaceutically acceptable suspensions, oils, creams, and ointments applied directly to the skin or incorporated into a protective carrier such as a transdermal device ("transdermal patch"). Examples of suitable creams, ointments, etc. can be found, for instance, in the Physician's Desk Reference. Examples of suitable transdermal devices are described, for instance, in U.S. Patent No. 4,818,540 issued April 4, 1989 to Chinen, et al.

Compositions of the peptide agents suitable for parenteral administration include, but are not limited to, pharmaceutically acceptable sterile isotonic solutions. Such solutions include, but are not limited to, saline and phosphate buffered saline for injection into a central venous line, intravenous, intramuscular, intraperitoneal, or subcutaneous injection of the peptides. Additional embodiments for parenteral application include injectable, sterile, oily solutions, suspensions, emulsions, or implants, including suppositories. Ampoules are convenient unit dosages.

Compositions of the peptide agents suitable for transbronchial and transalveolar administration include, but not limited to, various types of aerosols for inhalation. Devices suitable for transbronchial and transalveolar administration of the peptide

agents are also embodiments. Such devices include, but are not limited to, atomizers and vaporizers. Many forms of currently available atomizers and vaporizers can be readily adapted to deliver peptide agents.

5 Compositions of the peptide agents suitable for gastrointestinal administration include, but not limited to, pharmaceutically acceptable powders, tablets, pills, dragees, capsules, drops, or liquids for ingestion and suppositories for rectal administration. A syrup, elixir, or the like can be used wherein a sweetened vehicle is employed.

10 Sustained, pro-drugs, or directed release compositions can be formulated, e.g., liposomes or those wherein the active compound is protected with differentially degradable coatings, e.g., by microencapsulation, multiple coatings, etc. It is also possible to freeze-dry the ligands and use the lyophilizates obtained, for example, for the preparation of products for injection.

15 Aspects of the invention also include a coating for medical equipment. Alternatively, the peptides can be impregnated into a polymeric medical device such as catheters, stents and prosthetics. Coatings suitable for use in medical devices can be provided by a powder containing the peptides or by polymeric coating into which the peptides are suspended. Suitable polymeric materials for coatings or devices are those which are physiologically acceptable and through which a therapeutically effective amount of the peptide agent can diffuse. Suitable polymers include, but are not limited to, polyurethane, polymethacrylate, polyamide, polyester, polyethylene, polypropylene, polystyrene, polytetrafluoroethylene, polyvinyl-chloride, cellulose acetate, silicone elastomers, collagen, silk, etc. Such coatings are described, for instance, in U.S. Patent No. 4,612,337, issued September 16, 1986 to Fox et al. which is incorporated herein by reference.

20 It will be appreciated that the actual preferred amounts of active compound in a specific case will vary according to the specific compound being utilized, the particular compositions formulated, the mode of application, and the particular situs and organism being treated. The materials and methods and the experiments presented above are detailed in Su et al., *Blood*, 93(11): 1-10 (1999) and Su et al., *J. Immunol.* 162: (1999) herein incorporated by reference. The example below discloses the materials and methods used to perform the experiments which determined that T20/DP178 and

25

30

fragments thereof modulate an inflammatory response by interacting with an FPR member.

EXAMPLE 1

5 *Cells and Reagents*

The T20/DP178 and its analogs were synthesized and purified by the Department of Biochemistry, Colorado State University, Fort Collins, CO., according to the published sequences. (See Lawless et al., *Biochemistry* 35: 13697 (1996), herein expressly incorporated by reference).

Some embodiments were acylated. The purity was 90% or more and the amino acid composition was confirmed by mass-spectrometer. The endotoxin levels in dissolved peptides were undetectable. The chemotactic peptide formyl-methionyl-leucyl-phenylalanine (fMLP) was purchased from Sigma (St. Louis, MO). The human peripheral blood mononuclear cells were isolated from leukopacks through the courtesy of Transfusion Medicine Department, NIH Clinical Center, Bethesda, MD. Monocytes were further purified (purity > 90%). Human neutrophils were purified from the same leukopacks with 3% dextran sedimentation with a purity of > 98%. Rat basophilic leukemia cells stably transfected with an epitope tagged receptor for chemotactic formyl peptides, FPR, (Ali et al., *J. Biol. Chem.* 268: 24247 (1993)) were a kind gift of Drs. H. Ali, R. Richardson and R. Snyderman, Duke University, NC. The cells were designated

30

ETFR and were grown in DMEM, 10% FCS and 0.8 mg/ml geneticin (G418) to maintain selection pressure.

Chemotaxis assays

5 Cell migration was assessed using a 48-well microchemotaxis chamber. Different concentrations of stimulants were placed in the wells of the lower compartment of the chamber (Neuro Probe, Cabin John, MA), the cell suspension was seeded in the wells of the upper compartment which was separated from the lower compartment by polycarbonate filters (Osmonics, Livermore, CA; 5 μ m-pore size for monocytes and neutrophils, 10 μ m pore-size for ETFR cells). The filter for ETFR cell migration were precoated with 50 μ g/ml collagen type I (Sigma) to favor the attachment of the cells. After incubation at 37°C (90 min for monocytes, 60 min for neutrophils and 300 min for ETFR cells), the filters were removed, stained and the cells migrating across the filters were counted by light microscopy after coding the samples. The experiments were performed at least 5 times with each cell type and the results are presented as the number of migrating cells per high power field or as chemotaxis indices (CI) representing the fold increase in the number of migrating cells in response to stimuli, over the spontaneous cell migration (in response to control medium). The significance of the increase in cell migration was analysed with Student's t test and CI equals 2 and higher is statistically significant compared to medium control (at least $p < 0.05$).

Calcium mobilization

25 Calcium mobilization was assayed by incubating 10⁷/ml of monocytes, neutrophils or ETFR cells in loading buffer containing 138 mM NaCl, 6 mM KCl, 1 mM CaCl₂, 10 mM HEPES (pH 7.4), 5 mM glucose, 0.1% BSA with 5 μ M Fura-2 (Sigma) at 37°C for 30 min. The dye-loaded cells were washed and resuspended in fresh loading buffer. The cells were then transferred into quartz cuvettes (10⁶ cells in 2 ml) which were placed in a luminescence spectrometer LS50 B (Perkin-Elmer Limited, Beaconsfield, England). Stimulants at different concentrations were added in a volume of 20 μ l to the cuvettes at indicated time points. The ratio of fluorescence at 340 and 380 nm wavelength was calculated using the FL WinLab program (Perkin Elmer). The

assays were performed at least 5 times and results from representative experiments are shown.

Phosphorylation of FPR and measurement of MAP kinase

5 Phosphorylation of FPR was examined by culturing [³²P]-orthophosphate (Amersham, Arlington Heights, IL) labeled ETFR cells (3 x 10⁶) in 100-mm tissue culture dishes as described by Ali et al., *J. Biol. Chem.* 268: 24247 (1993). After stimulation with fMLP or T20/DP178, the cells were lysed and immunoprecipitation was performed by using an anti-HA antibody (12CA5) (Boehringer-Mannheim, Indianapolis, IN) and protein G sepharose (Pharmacia, Uppsala, Sweden). The immune complexes then were eluted with SDS-PAGE sample buffer (Novex, San Diego, CA) and subjected SDS-PAGE and autoradiography.

10 MAP kinase activation was measured as described previously. (Krump et al., *J. Biol. Chem.* 272: 937 (1997)). Briefly, following stimulation of human monocytes with T20/DP178, the cells were solubilized and a specific anti-p38 MAPK antibody (New England Biolabs, Beverly, MA) was added to the soluble fraction followed by addition of protein A-Sepharose (Pharmacia). The immune complexes bound to sepharose were eluted with SDS-PAGE loading buffer. After electrophoresis, the immune complexes were electrotransferred onto polyvinylidene difluoride (PVDF) membranes (Millipore Corporation, Bedford, MA) which were reacted with a mouse anti-phosphotyrosine antibody followed by a horseradish peroxidase-coupled anti-mouse antibody (New England Biolabs Inc., 1:5,000 dilution). The MAPK was finally detected by enhanced chemiluminescence (ECL; Amersham).

Binding assays

25 Tritiated (³H) fMLP was purchased from Dupont NEN (Boston, MA). A single concentration of ³H-fMLP (1 nCi) was added simultaneously with different concentrations of unlabeled agonists into 200 µl cell suspension (2 X 10⁶ phagocytes or ETFR cells) in duplicate samples. The samples were incubated under constant rotation for 20 min at 37°C. After incubation, the samples were filtered onto Whatman GF/C fiber discs (Whatman International Ltd., Kent, UK) on a 12-well manifold followed by extensive washing with ice-cold PBS. The discs were air-dried at 65°C and then were

submerged in liquid scintillation cocktail and counted for β emission. The binding assays were performed 3 times. The rate of inhibition was calculated by the formula:

$$5 \quad 1 - \frac{\text{cpm obtained in the presence of unlabeled agonist}}{\text{cpm in the absence of unlabeled agonist}} \times 100\%$$

In the following example, we disclose the materials and methods used to perform the experiments which determined that T21/DP107 and fragments thereof modulate an inflammatory response by interacting with an FPR member.

EXAMPLE 2

Reagents and cells

15 The T21/DP107 was synthesized and purified by the Department of Biochemistry, Colorado State University, Fort Collins, Co., according to the published sequence (aa 558 - 595 of gp41). (See Lawless et al., *Biochemistry* 35: 13697 (1996), herein expressly incorporated by reference).

T21/DP107: NNLLRAIEAQQHLLQLTVWGIKQLQARILAVEERYLKDQ
20 SEQ ID NO:202

Some embodiments were acylated. The purity was 90% or more and the amino acid composition was verified by mass-spectrometer. The endotoxin levels in dissolved peptide were undetectable. The synthetic formyl peptide fMLP was purchased from Sigma (St. Louis, MO). The human peripheral blood mononuclear cells were isolated from leukopacks through the courtesy of Transfusion Medicine Department, NIH Clinical Center, Bethesda, MD. Monocytes were further purified by elutriation to yield > 90% purity. Human polymorph neutrophils were purified from the same leukopacks by 3% dextran sedimentation with a purity of > 98%. Rat basophilic leukemia cells stably transfected with Epitope tagged FPR (ETFR) were a kind gift of Drs. H. Ali and R. Snyderman, Duke University, NC. The cells were designated ETFR and were grown in DMEM, 10% FCS and 0.8 mg/ml geneticin (G418) to maintain selection pressure. The FPR-like receptor 1 (FPRL1) cDNA was cloned and transfected into human

30

embryonic kidney cells (HEK) 293 (designated FPRL1/293 cells) as reported previously. (Gao and M. Murphy, *J. Biol. Chem.* 268: 25395 (1993)). The cells were maintained in DMEM, 10% FCS and 2 mg/ml geneticin (G418).

5 *Chemotaxis*

Leukocytes, ETFR and FPRL1/293 cell migration was assessed using a 48-well microchemotaxis chamber technique as previously described. (Gong et al., *J. Biol. Chem.* 273: 4289 (1998); Gong et al., *J. Biol. Chem.* 272: 11682 (1997); and Kliger et al., *J. Biol. Chem.* 272: 13496 (1997)). Different concentrations of stimulants were placed in wells of the lower compartment of the chamber (Neuro Probe, Cabin John, MA), the cell suspension was seeded in wells of the upper compartment which was separated from the lower compartment by a polycarbonate filter (Osmonics, Livermore, CA; 5 µm-pore size for leukocytes, 10 µm pore-size for ETFR and FPRL1/293 cells). For CD3⁺ T lymphocytes, the filters were precoated with 20 µg/ml bovine fibronectin (Sigma). The filters for ETFR and FPRL1/293 cell migration were precoated with 50 µg/ml collagen type I (Collaborative Biomedical products, Bedford, MA) to favor the attachment of the cells. After incubation at 37°C (90 min for monocytes, 60 min for neutrophils, 180 min for T cells and 300 min for ETFR or FPRL1/293 cells), the filters were removed, stained and the cells migrating across the filter were counted by light microscopy after coding the samples. The experiments were performed at least 5 times with each cell type and the results are presented as the chemotaxis indexes (CI) representing the fold increase in the number of migrating cells in response to stimuli, over the spontaneous cell migration (in response to control medium). The significance of the increase in cell migration was determined using Student's t test and $CI \geq 2$ was statistically significant compared to medium control (at least $p < 0.05$).

Calcium mobilization

Calcium mobilization was assayed by incubating 10⁷/ml of monocytes, neutrophils, FPRL1 or ETFR transfectants in loading buffer containing 138 mM NaCl, 6 mM KCl, 1 mM CaCl₂, 10 mM HEPES (pH 7.4), 5 mM glucose, 0.1% BSA with 5 µM Fura-2 (Sigma) at 37°C for 30 min. The dye-loaded cells were washed and resuspended in fresh loading buffer. The cells were then transferred into quartz cuvettes

(106 cells in 2 ml) which were placed in a luminescence spectrometer LS50 B (Perkin-Elmer Limited, Beaconsfield, England). Stimulants at different concentrations were added in a volume of 20 μ l to the cuvettes at indicated time points. The ratio of fluorescence at 340 and 380 nm wavelength was calculated using the FL WinLab program (Perkin Elmer).

Unless specified, all experiments were performed at least five times with similar results and the data shown were from representative experiments.

Although the invention has been described with reference to embodiments and examples, it should be understood that various modifications can be made without departing from the spirit of the invention. Accordingly, the invention is limited only by the following claims. All references cited herein are hereby expressly incorporated by reference.
